How to Submit

Step 1 of 2

Step 2 of 2

Objectives

- Allow you to design and implement your own data structure.
- Optimize your code's (real-world) running time.

Recommended Reading

- Pages 18 20, 27 30, 33, 36, and 37 of http://www.howstuffworks.com/c.htm (http://www.howstuffworks.com/c.htm).
- Chapter 26 of Absolute Beginner's Guide to C.
- Chapter 17 of Programming in C.

Academic Honesty

This course's philosophy on academic honesty is best stated as "be reasonable." The course recognizes that interactions with classmates and others can facilitate mastery of the course's material. However, there remains a line between enlisting the help of another and submitting the work of another. This policy characterizes both sides of that line.

The essence of all work that you submit to this course must be your own. Collaboration on problem sets is not permitted except to the extent that you may ask classmates and others for help so long as that help does not reduce to another doing your work for you. Generally speaking, when asking for help, you may show your code to others, but you may not view theirs, so long as you and they respect this policy's other constraints. Collaboration on quizzes is not permitted at all. Collaboration on the course's final project is permitted to the extent prescribed by its specification.

Below are rules of thumb that (inexhaustively) characterize acts that the course considers reasonable and not reasonable. If in doubt as to whether some act is reasonable, do not commit it until you solicit and receive approval in writing from the course's heads. Acts considered not reasonable by the course are handled harshly. If the course refers some matter for disciplinary action and the outcome is punitive, the course reserves the right to impose local sanctions on top of that outcome that may include an unsatisfactory or failing grade for work submitted or for the course itself.

If you commit some act that is not reasonable but bring it to the attention of the course's heads within 72 hours, the course may impose local sanctions that may include an unsatisfactory or failing grade for work submitted, but the course will not refer the matter for further disciplinary action except in cases of repeated acts.

Reasonable

- Communicating with classmates about problem sets' problems in English (or some other spoken language).
- Discussing the course's material with others in order to understand it better.
- Helping a classmate identify a bug in his or her code at office hours, elsewhere, or even online, as by viewing, compiling, or running his or her code, even on your own computer.
- Incorporating snippets of code that you find online or elsewhere into your own code, provided that those snippets are not themselves solutions to assigned problems and that you cite the snippets' origins.
- Reviewing past semesters' guizzes and solutions thereto.
- Sending or showing code that you've written to someone, possibly a classmate, so that he or she might help you identify and fix a bug.
- Sharing snippets of your own code online so that others might help you identify and fix a bug.
- Turning to the web or elsewhere for instruction beyond the course's own, for references, and for solutions to technical difficulties, but not for outright solutions to problem set's problems or your own final project.
- Whiteboarding solutions to problem sets with others using diagrams or pseudocode but not actual code.
- Working with (and even paying) a tutor to help you with the course, provided the tutor does not do your work for you.

Not Reasonable

- Accessing a solution to some problem prior to (re-)submitting your own.
- · Asking a classmate to see his or her solution to a problem set's problem before (re-)submitting your own.
- Decompiling, deobfuscating, or disassembling the staff's solutions to problem sets.
- Failing to cite (as with comments) the origins of code or techniques that you discover outside of the course's own lessons and integrate into your own work, even while respecting this policy's other constraints.
- Giving or showing to a classmate a solution to a problem set's problem when it is he or she, and not you, who is struggling to solve it.
- Looking at another individual's work during a quiz.
- Paying or offering to pay an individual for work that you may submit as (part of) your own.
- Providing or making available solutions to problem sets to individuals who might take this course in the future.
- Searching for, soliciting, or viewing a quiz's questions or answers prior to taking the quiz.
- Searching for or soliciting outright solutions to problem sets online or elsewhere.
- Splitting a problem set's workload with another individual and combining your work.
- Submitting (after possibly modifying) the work of another individual beyond allowed snippets.

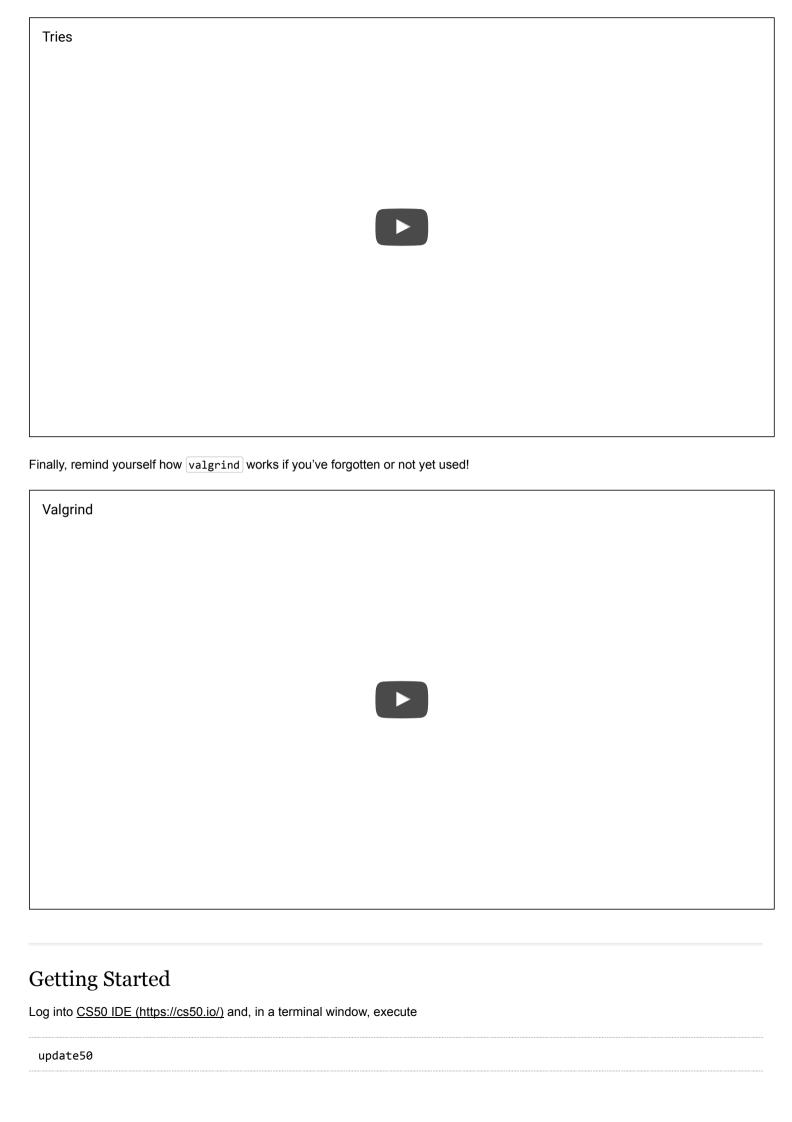

- Submitting the same or similar work to this course that you have submitted or will submit to another.
- Submitting work to this course that you intend to use outside of the course (e.g., for a job) without prior approval from the course's heads.
- Using resources during a quiz beyond those explicitly allowed in the quiz's instructions.
- Viewing another's solution to a problem set's problem and basing your own solution on it.

Getting Ready

First, join Jackson and Lauren for tours of singly linked lists and hash tables.

Next, join Kevin for a tour of tries.

Like Problem Set 4, this problem set comes with some distribution code that you'll need to download before getting started. Go ahead and execute
cd ~/workspace
in order to navigate to your ~/workspace directory. Then execute
wget http://cdn.cs50.net/2015/fall/psets/5/pset5/pset5.zip
in order to download a ZIP (i.e., compressed version) of this problem set's distro. If you then execute
ls
you should see that you now have a file called pset5.zip in your \(\textstyle \)/workspace directory. Unzip it by executing the below.
unzip pset5.zip
If you again execute
ls
you should see that you now also have a pset5 directory. You're now welcome to delete the ZIP file with the below.
rm -f pset5.zip
Now dive into that pset5 directory by executing the below.
cd pset5
Now execute
ls
and you should see that the directory contains the below.
dictionaries/ dictionary.c dictionary.h keys/ Makefile questions.txt speller.c texts/
Interesting!

to ensure that your workspace is up-to-date!

Anyhow, theoretically, on input of size n, an algorithm with a running time of n is asymptotically equivalent, in terms of O, to an algorithm with a running time of 2n. In the real world, though, the fact of the matter is that the latter feels twice as slow as the former.

The challenge ahead of you is to implement the fastest spell-checker you can! By "fastest," though, we're talking actual, real-world, noticeable time—none of that asymptotic stuff this time.

In speller.c, we've put together a program that's designed to spell-check a file after loading a dictionary of words from disk into memory. Unfortunately, we didn't quite get around to implementing the loading part. Or the checking part. Both (and a bit more) we leave to you!

Before we walk you through <code>speller.c</code>, go ahead and open up <code>dictionary.h</code>. Declared in that file are four functions; take note of what each should do. Now open up <code>dictionary.c</code>. Notice that we've implemented those four functions, but only barely, just enough for this code to compile. Your job for this problem set is to re-implement those functions as cleverly as possible so that this spell-checker works as advertised. And fast!

Let's get you started.

Makefile

Recall that make automates compilation of your code so that you don't have to execute clang manually along with a whole bunch of switches. However, as your programs grow in size, make won't be able to infer from context anymore how to compile your code; you'll need to start telling make how to compile your program, particularly when they involve multiple source (i.e., c) files, as in the case of this problem set. And so we'll utilize a Makefile, a configuration file that tells make exactly what to do. Open up Makefile, and let's take a tour of its lines.

The line below defines a variable called CC that specifies that make should use clang for compiling.

```
CC = clang
```

The line below defines a variable called CFLAGS that specifies, in turn, that clang should use some flags, most of which should look familiar.

```
CFLAGS = -ggdb3 -00 -Qunused-arguments -std=c11 -Wall -Werror
```

The line below defines a variable called EXE, the value of which will be our program's name.

```
EXE = speller
```

The line below defines a variable called HDRS, the value of which is a space-separated list of header files used by speller.

```
HDRS = dictionary.h
```

The line below defines a variable called LIBS, the value of which is should be a space-separated list of libraries, each of which should be prefixed with -1. (Recall our use of -1cs50 earlier this term.) Odds are you won't need to enumerate any libraries for this problem set, but we've included the variable just in case.

```
LIBS =
```

The line below defines a variable called <code>SRCS</code>, the value of which is a space-separated list of C files that will collectively implement speller.

```
SRCS = speller.c dictionary.c
```

The line below defines a variable called OBJS, the value of which is identical to that of SRCS, except that each file's extension is not but .o.

```
OBJS = \$(SRCS:.c=.o)
```

The lines below define a "target" using these variables that tells make how to compile speller.

```
$(EXE): $(OBJS) Makefile
$(CC) $(CFLAGS) -o $@ $(OBJS) $(LIBS)
```

The line below specifies that our of files all "depend on" dictionary.h and Makefile so that changes to either induce recompilation of the former when you run make.						
<pre>\$(OBJS): \$(HDRS) Makefile</pre>						
Finally, the lines below define another target for cleaning up this problem set's directory.						
clean: rm -f core \$(EXE) *.o						
Know that you're welcome to modify this Makefile as you see fit. In fact, you should if you create any .c or .h files of your own. But be sure not to change any tabs (i.e., \t) to spaces, since make expects the former to be present below each target.						
The net effect of all these lines is that you can compile speller with a single command, even though it comprises quite a few files:						
make speller						
Even better, you can also just execute:						
make						
And if you ever want to delete speller plus any core or .o files, you can do so with a single command:						
make clean						
In general, though, anytime you want to compile your code for this problem set, it should suffice to run:						
make						
speller.c						
Okay, next open up speller.c and spend some time looking over the code and comments therein. You won't need to change anything in this file, but you should understand it nonetheless. Notice how, by way of getrusage, we'll be "benchmarking" (i.e., timing the execution of) your implementations of check, load, size, and unload. Also notice how we go about passing check, word by word, the contents of some file to be spell-checked. Ultimately, we report each misspelling in that file along with a bunch of statistics.						
Notice, incidentally, that we have defined the usage of speller to be						
Usage: speller [dictionary] text						
where dictionary is assumed to be a file containing a list of lowercase words, one per line, and text is a file to be spell-checked. As the brackets suggest, provision of dictionary is optional; if this argument is omitted, speller will use dictionaries/large by default. In other words, running						
./speller text						
will be equivalent to running						
./speller dictionaries/large text						
where text is the file you wish to spell-check. Suffice it to say, the former is easier to type! (Of course, speller will not be able to load any dictionaries until you implement load in dictionary.c! Until then, you'll see Could not load .)						

Within the default dictionary, mind you, are 143,091 words, all of which must be loaded into memory! In fact, take a peek at that file to get a sense of its structure and size. Notice that every word in that file appears in lowercase (even, for simplicity, proper nouns and acronyms). From top to bottom, the file is sorted lexicographically, with only one word per line (each of which ends with \n). No word is longer than 45 characters, and no word appears more than once. During development, you may find it helpful to provide speller with a dictionary of your own that contains far fewer words, lest you struggle to debug an otherwise enormous structure in memory. In dictionaries/small is one such dictionary. To use it, execute

./speller dictionaries/small text

where text is the file you wish to spell-check. Don't move on until you're sure you understand how speller itself works!

Odds are, you didn't spend enough time looking over speller.c. Go back one square and walk yourself through it again!

questions.txt

Okay, technically that last problem induced an infinite loop. But we'll assume you broke out of it. Open up questions.txt and answer each of the following questions in one or more sentences.

- 0. What is pneumonoultramicroscopicsilicovolcanoconiosis?
- 1. According to its man page, what does getrusage do?
- 2. Per that same man page, how many members are in a variable of type struct rusage?
- 3. Why do you think we pass before and after by reference (instead of by value) to calculate, even though we're not changing their contents?
- 4. Explain as precisely as possible, in a paragraph or more, how main goes about reading words from a file. In other words, convince us that you indeed understand how that function's for loop works.
- 5. Why do you think we used fgetc to read each word's characters one at a time rather than use fscanf with a format string like "%s" to read whole words at a time? Put another way, what problems might arise by relying on fscanf alone?
- 6. Why do you think we declared the parameters for check and load as const?

texts

So that you can test your implementation of speller, we've also provided you with a whole bunch of texts, among them the script from *Austin Powers: International Man of Mystery*, a sound bite from Ralph Wiggum, three million bytes from Tolstoy, some excerpts from Machiavelli and Shakespeare, the entirety of the King James V Bible, and more. So that you know what to expect, open and skim each of those files, all of which are in a directory called texts within your pset5 directory.

Now, as you should know from having read over speller.c carefully, the output of speller, if executed with, say,

./speller texts/austinpowers.txt

will eventually resemble the below. For now, try executing the staff's solution (using the default dictionary) with the below.

~cs50/pset5/speller texts/austinpowers.txt

Below's some of the output you'll see. For amusement's sake, we've excerpted some of our favorite "misspellings." And lest we spoil the fun, we've omitted our own statistics for now.

MISSPELLED WORDS
[] Bigglesworth
Virtucon
[]
friggin'
[] trippy
$[\cdots]$
[]
WORDS MISSPELLED:
WORDS IN DICTIONARY:
WORDS IN TEXT:
TIME IN load:
TIME IN check:
TIME IN size:
TIME IN unload:
TIME IN TOTAL:
TIME IN load represents the number of seconds that speller spends executing your implementation of load. TIME IN check represents the number of seconds that speller spends, in total, executing your implementation of check. TIME IN size represents the number of seconds that speller spends executing your implementation of size. TIME IN unload represents the number of seconds that speller spends executing your implementation of unload. TIME IN TOTAL is the sum of those four measurements.
you don't change your code. Incidentally, to be clear, by "misspelled" we simply mean that some word is not in the dictionary provided. And now this:
Newscasters Agree: Yeah, Baby Edition

Spell Checking

Alright, the challenge now before you is to implement <code>load</code>, <code>check</code>, <code>size</code>, and <code>unload</code> as efficiently as possible, in such a way that <code>TIME IN load</code>, <code>TIME IN check</code>, <code>TIME IN size</code>, and <code>TIME IN unload</code> are all minimized. To be sure, it's not obvious what it even means to be minimized, inasmuch as these benchmarks will certainly vary as you feed <code>speller</code> different values for <code>dictionary</code> and for <code>text</code>. But therein lies the challenge, if not the fun, of this problem set. This problem set is your chance to design. Although we invite you to minimize space, your ultimate enemy is time. But before you dive in, some specifications from us.

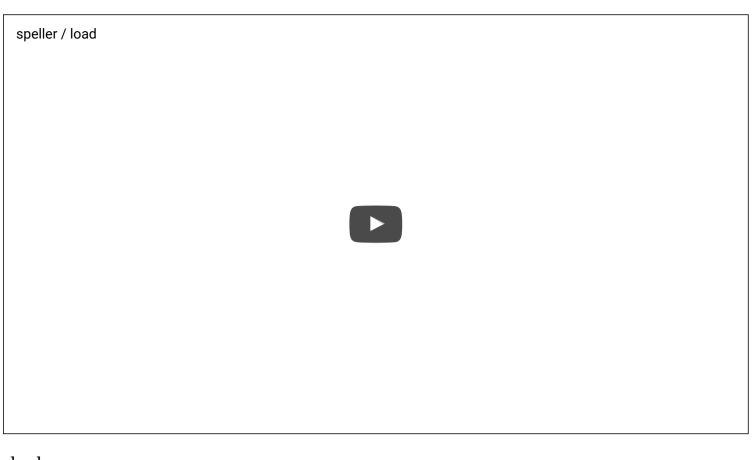

- You may not alter speller.c.
- You may alter dictionary.c (and, in fact, must in order to complete the implementations of load, check, size, and unload), but you may not alter the declarations of load, check, size, or unload.
- You may alter dictionary.h, but you may not alter the declarations of load, check, size, or unload.
- You may alter Makefile.
- You may add functions to dictionary.c or to files of your own creation so long as all of your code compiles via make.
- Your implementation of check must be case-insensitive. In other words, if foo, fo
- Capitalization aside, your implementation of check should only return true for words actually in dictionary. Beware hard-coding common words (e.g., the), lest we pass your implementation a dictionary without those same words. Moreover, the only possessives allowed are those actually in dictionary. In other words, even if foo is in dictionary, check should return false given foo's if foo's is not also in dictionary.
- You may assume that check will only be passed strings with alphabetical characters and/or apostrophes.
- You may assume that any dictionary passed to your program will be structured exactly like ours, lexicographically sorted from top to bottom with one word per line, each of which ends with \n. You may also assume that dictionary will contain at least one word, that no word will be longer than LENGTH (a constant defined in dictionary.h) characters, that no word will appear more than once, and that each word will contain only lowercase alphabetical characters and possibly apostrophes.
- Your spell-checker may only take text and, optionally, dictionary as input. Although you might be inclined (particularly if among those more comfortable) to "pre-process" our default dictionary in order to derive an "ideal hash function" for it, you may not save the output of any such pre-processing to disk in order to load it back into memory on subsequent runs of your spell-checker in order to gain an advantage.
- You may research hash functions in books or on the Web, so long as you cite the origin of any hash function you integrate into your own code.

Alright, ready to go?

load

Implement load!

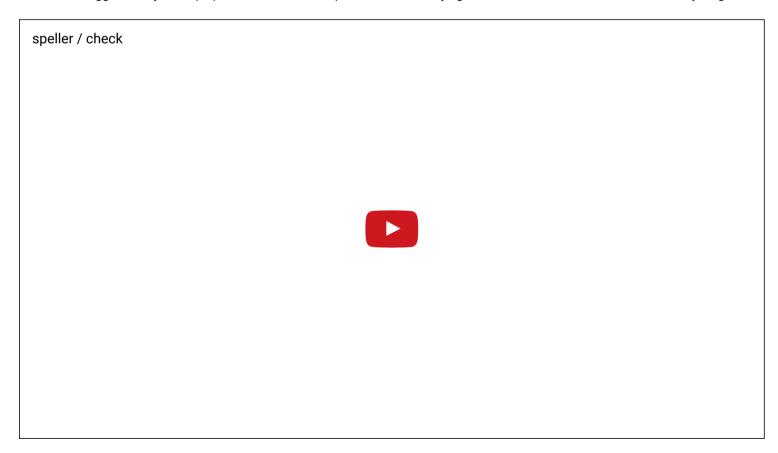

Allow us to suggest that you whip up some dictionaries smaller than the 143,091-word default with which to test your code during development. And here's Zamyla with some additional guidance:

check

Implement check !

Allow us to suggest that you whip up some small files to spell-check before trying out, oh, War and Peace. And here's Zamyla again:

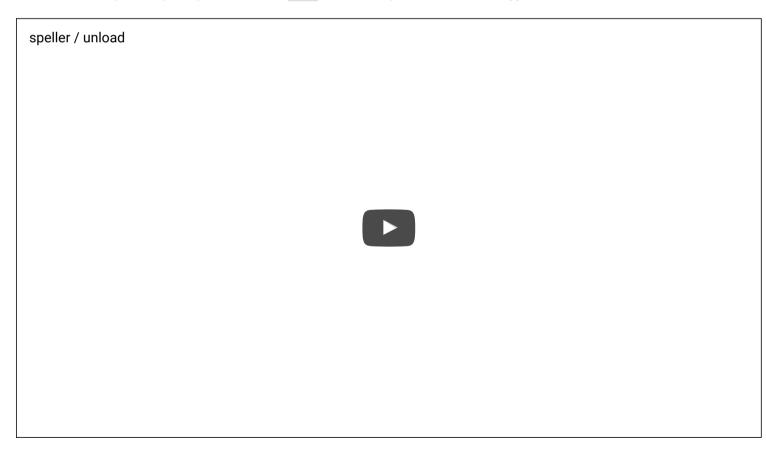

size

Implement size!

If you planned ahead, this one is easy! Here's Zamyla!

speller / size		
'		
unload		
Implement unload!		

Be sure to free any memory that you allocated in <code>load!</code> Here's Zamyla with some final suggestions!

In fact, be sure that your spell-checker doesn't leak any memory at all. Recall that valgrind is your newest best friend. Know that valgrind watches for leaks while your program is actually running, so be sure to provide command-line arguments if you want valgrind to analyze speller while you use a particular dictionary and/or text, as in the below.

If you run valgrind without specifying a text for speller, your implementations of load and unload won't actually get called (and thus analyzed).

And don't forget about your other good buddy, gdb.

Checking Spell Checking

How to check whether your program is outling the right misspelled words? Well, you're welcome to consult the "answer keys" that are inside of the keys directory that's inside of your pset5 directory. For instance, inside of keys/austinpowers.txt are all of the words that your program should think are misspelled.

You could therefore run your program on some text in one window, as with the below.

./speller texts/austinpowers.txt

And you could then run the staff's solution on the same text in another window, as with the below.

~cs50/pset5/speller texts/austinpowers.txt

And you could then compare the windows visually side by side. That could get tedious quickly, though. So you might instead want to "redirect" your program's output to a file (just like you may have done with generate in Problem Set 3), as with the below.

```
./speller texts/austinpowers.txt > student.txt
~cs50/pset5/speller texts/austinpowers.txt > staff.txt
```

You can then compare both files side by side in the same window with a program like diff, as with the below.

```
diff -y student.txt staff.txt
```

Alternatively, to save time, you could just compare your program's output (assuming you redirected it to, e.g., student.txt) against one of the answer keys without running the staff's solution, as with the below.

```
diff -y student.txt keys/austinpowers.txt
```

If your program's output matches the staff's, diff will output two columns that should be identical except for, perhaps, the running times at the bottom. If the columns differ, though, you'll see a so or where they differ. For instance, if you see

```
MISSPELLED WORDS

FOTTAGE
INT
INT
SEVIL'S
S
S
Farbissina

MISSPELLED WORDS
```

that means your program (whose output is on the left) does not think that <code>EVIL's</code> is misspelled, even though the staff's output (on the right) does, as is implied by the absence of <code>EVIL's</code> in the lefthand column and the presence of <code>EVIL's</code> in the righthand column.

To test your code less manually (though still not exhaustively), you may also execute the below.

Note that check50 does not check for memory leaks, so be sure to run valgrind as prescribed as well.

How to assess just how fast (and correct) your code is? Well, as always, feel free to play with the staff's solution, as with the below, and compare its numbers against yours.

~cs50/pset5/speller texts/austinpowers.txt

Big Board

Afraid the Big Board is only operational on campus!

questions.txt

Congrats! At this point, your speller-checker is presumably complete (and fast!), so it's time for a debriefing. In questions.txt, answer each of the following questions in a short paragraph.

- 7. What data structure(s) did you use to implement your spell-checker? Be sure not to leave your answer at just "hash table," "trie," or the like. Expound on what's inside each of your "nodes."
- 8. How slow was your code the first time you got it working correctly?
- 9. What kinds of changes, if any, did you make to your code in order to improve its performance?
- 10. Do you feel that your code has any bottlenecks that you were not able to chip away at?

How to Submit

Step 1 of 2

- 1. When ready to submit, log into CS50 IDE (https://cs50.io/).
- 2. Toward CS50 IDE's top-left corner, within its "file browser" (not within a terminal window), control-click or right-click pset5 folder and then select **Download**. You should find that your browser has downloaded pset5.zip.
- 3. In a separate tab or window, log into CS50 Submit (http://cs50.edx.org/submit), logging in if prompted.
- 4. Click Submit toward the window's top-left corner.
- 5. Under Problem Set 5 on the screen that appears, click Upload New Submission.
- 6. On the screen that appears, click **Add files...**. A window entitled **Open Files** should appear.
- 7. Navigate your way to pset5.zip. Odds are it's in your **Downloads** folder or wherever your browser downloads files by default. Once you find pset5.zip, click it once to select it, then click **Open** (or the like).
- 8. Click Start upload to upload all of your files at once to CS50's servers.
- 9. On the screen that appears, you should see a window with **No File Selected**. If you move your mouse toward the window's lefthand side, you should see a list of the files you uploaded. Click each to confirm the contents of each. (No need to click any other buttons or icons.) If confident that you submitted the files you intended, consider your source code submitted! If you'd like to re-submit different (or modified) files, simply return to <u>CS50 Submit (http://cs50.edx.org/submit)</u> and repeat these steps. You may re-submit as many times as you'd like; we'll grade your most recent submission, so long as it's before the deadline.

Step 2 of 2

Head to http://cs50.edx.org/2016/psets/5/) where a short form awaits. Once you have submitted that form (as well as your source code), you are done! If you end up resubmitting your files (per step 1 of 2), no need to resubmit the form.

This was Problem Set 5.
